20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

About 1,235 square kilometers of the Inner Continental Shelf adjacent to Cape May peninsula was investigated by a seismic reflection and coring survey to obtain geologic information on sea floor and subbottom sand and gravel deposits having suitable characteristics for use as fill in beach nourishment and restoration projects. Water depths in the study area ranged from about 1.5 to 21 meters. A total of 1,258 kilometers of seismic profiles and 104 vibratory cores, ranging in length from 1 to 3.7 meters, were examined.

SECURITY CLASSIFICATION OF THIS PAGE (When Data Entered)

Linear and arcuate shoals are the dominant sea floor features in the region and most appear to be composed of clean, fine to very coarse-grained quartz sand which overlies a flat deposition surface. Several cores penetrating the surface show the underlying material to be a poorly sorted admixture of fine-grained and very coarse-grained sediments that are denser than the modern shelf sands and probably represent a pre-Holocene fluvial deposit.

Results of this assessment study show that 16 potential shoal sites and 2 promising sea floor areas are present. Individual shoals contain from 4.6 to more than 472 million cubic meters of sand; the total sand and gravel resource is conservatively estimated to be 1,086 million cubic meters.

PREFACE

This report is one of a series presenting results of the Inner Continental Shelf Sediment and Structure (ICONS) study. The primary objective of the ICONS study is locating and delineating offshore sand and gravel deposits suitable for beach nourishment and restoration. The work was carried out under the coastal processes program of the U.S. Army Coastal Engineering Research Center (CERC).

The report was prepared by Edward P. Meisburger and S. Jeffress Williams, CERC geologists, under the general supervision of Dr. C.H. Everts, Chief, Engineering Geology Branch, Engineering Development Division (EDD). As part of the research program of EDD, the ICONS study is under the general supervision of N. Parker, Chief of the Division. The fieldwork (obtaining cores and continuous seismic reflection profile records) was accomplished under contract by Alpine Geophysical Associates, Inc.

Microfilm copy of all seismic data is stored at the National Solar and Terrestrial Geophysical Data Center (NSTGDC), Rockville, Maryland 20852. Cores collected during the field survey program are in a repository at the University of Texas, Arlington, Texas 76010, under agreement with CERC. Requests for information relative to these items should be directed to NSTGDC or the University of Texas.

Comments on this publication are invited.

Approved for publication in accordance with Public Law 166, 79th Congress, approved 31 July 1945, as supplemented by Public Law 172, 88th Congress, approved 7 November 1963.

SAND RESOURCES ON THE INNER CONTINENTAL SHELF OF THE CAPE MAY REGION, NEW JERSEY

by
Edward P. Meisburger and S. Jeffress Williams

I. INTRODUCTION

1. Background.

Initial restoration and periodic renourishment of beaches and dunes by placement of suitable sand along the shoreline is an effective means of counteracting coastal erosion and of enhancing recreational facilities (U.S. Army, Corps of Engineers, Coastal Engineering Research Center, 1977). In recent years, it has become increasingly difficult to obtain large volumes of suitable sand from lagoons and inland sources for beach nourishment because of economic and ecological factors. Accordingly, the Coastal Engineering Research Center (CERC) initiated an Inner Continental Shelf Sediment and Structure (ICONS) study program to locate and describe offshore sand resources suitable for beach nourishment. This report, a result of that effort, deals with the location and physical characteristics of offshore sand resources near Cape May, New Jersey.

2. Study Location and Data Coverage.

The ICONS study area comprises a 27.8- by 44.5-kilometer region of sea floor lying to the south and southeast of Cape May, New Jersey (Fig. 1). Data coverage in this area consists of 1,258 kilometers of seismic reflection surveys and 104 sediment cores ranging from 1 to 3.7 meters in length (Fig. 2). These data were supplemented by National Ocean Survey (NOS) hydrographic chart data.

This report is primarily the result of a reconnaissance effort; seismic line spacing and core density are not detailed enough for precise delineation of borrow sites. Consequently, more detailed study of promising locales identified in this report will be needed before specific borrow sites are identified for use in project design and construction.

3. Regional Setting and Sea Floor Morphology.

The study area, located at the southern end of the New Jersey coast within the New York Bight (longitude 75°02'30" to 74°30" W. and latitude 39° to 38°46' N.), is part of the Atlantic Coastal Plain province of eastern North America. The area is bounded to the north by Cape May peninsula, a headland section of the New Jersey coast, and to the west by the low-lying Delaware coast and the Delaware River shelf channel as defined by the 18.3-meter (60 feet) depth contour in Figure 1. The region surveyed covers about 1,166 square kilometers of the Inner Continental Shelf extending from the Cape May shoreface seaward to depths of about 37 meters (120 feet).

The coast of New Jersey can be divided basically into two physiographic parts. The northern part from Monmouth Beach to near Bay Head is a headland where older coastal deposits are in direct contact with the sea. The central part of the coast, including Sandy Hook spit protruding into New York harbor, is composed of low-lying sandy barrier islands and spits backed by shallow lagoons. The barriers are fairly continuous except for nine tidal inlets, and

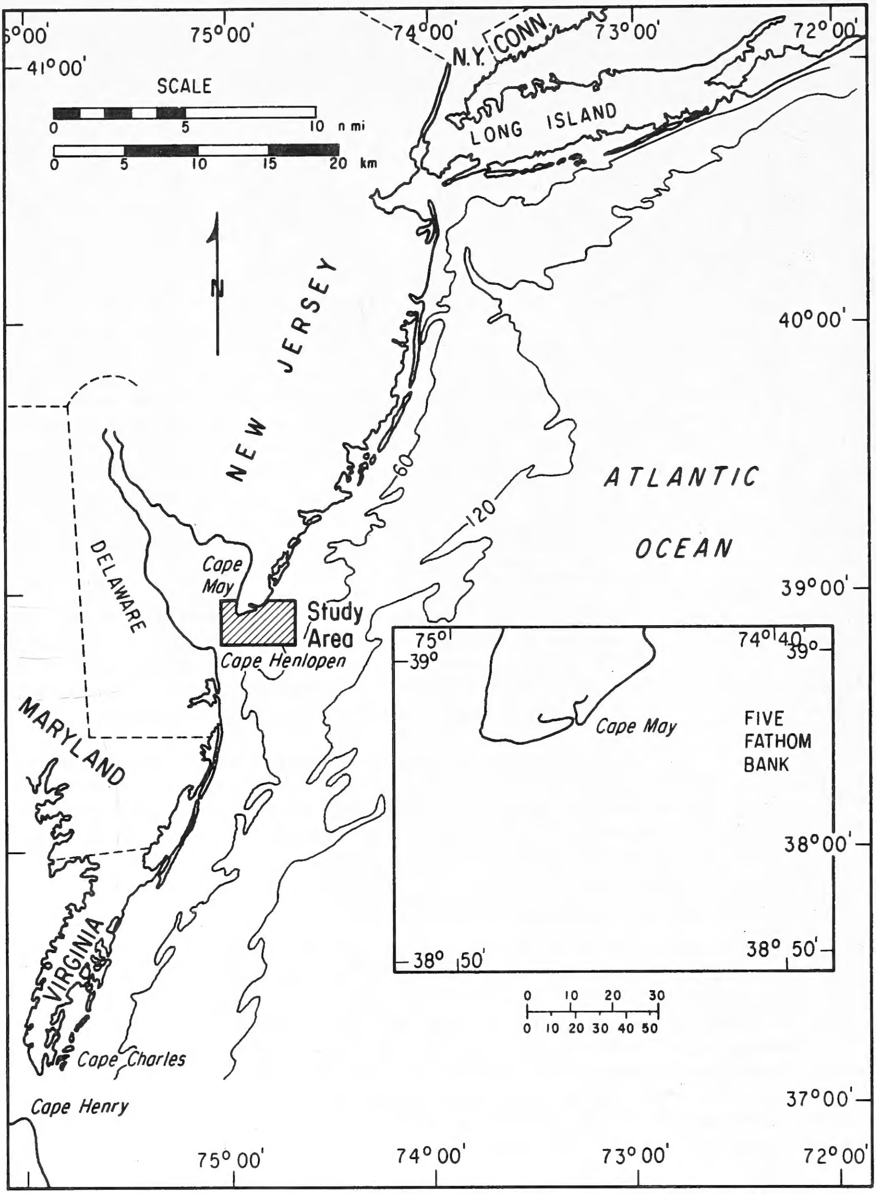

Figure 1. Cape May ICONS study area.

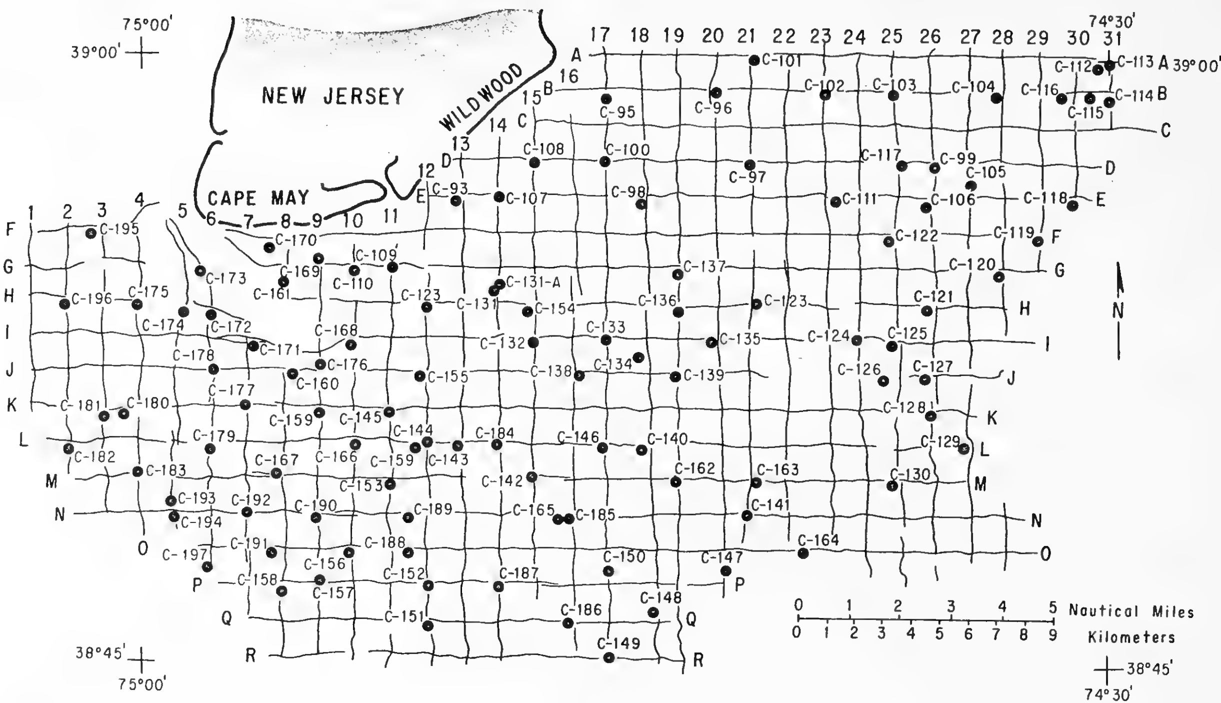

Figure 2. Location of seismic reflection profiles and vibratory cores used to access submarine sand resources.

extend in an irregular line south to Cape May city. The tip of Cape May peninsula from Cape May city west to Delaware Bay is also a headland where pre-Holocene sediments are directly exposed to coastal erosion.

The sea floor contours in Figure 3 show a very complex pattern, but the general ridge and swale topography trends northeast-southwest east of about longitude 74°45' W., whereas to the west the shoals are arcuate and parallel the Cape May coast. Five Fathom Bank (shown by the 2-meter (-36 feet) contour in Figure 3) is an exception to either fabric by its north-south orientation and probably owes its origin to processes that are different from those that form and modify most shoals in the area. The shoals on the Delaware shelf west of the Delaware Channel are quite different in orientation by trending to the northwest.

4. Sediments.

Sediments recovered from cores of the study area can be divided into two general age groups. The younger group consists of Holocene marine sediments which are distinguished by their small content of invertebrate remains; the presumably older group of sediments is mostly barren of animal remains. The most abundant Holocene deposit is a clean, pale-brown quartz sand, locally with admixtures of granules and pebbles. Sand size ranges from fine to very coarse (Wentworth Scale in Table 1). Sorting is predominantly poor especially in the coarser sand faces. Also included in the presumed Holocene deposits are silt, clay, and silty, sandy gravel which are probably relict transgressive back-barrier or reworked deposits from older substrate.

Below the Holocene sediments is a diverse group of pre-Holocene sediments consisting of sands, sandy gravel, silt, and clay. These deposits are complexly distributed with little vertical or lateral continuity. Although pre-Holocene sediments of similar character occur throughout the area, available data suggest that these deposits are not directly connected but rather that lithologic similarities are due to common source areas and recurrence of similar depositional conditions. The heterogeneous character and highly discontinuous distribution of these sediments suggest fluvial deposition. Nonmarine depositional conditions are also suggested by the absence of any marine organic remains, although this could be due to leaching.

Sediments recovered by cores taken during the ICONS survey are described in the visual core logs of Appendix A. Grain-size data for selected surveys are presented in Appendix B. Most of the sediments can be grouped in a number of characteristic types (summarized in Table 2); letters keyed to these types are used in the log descriptions (App. A) to identify sediments which correspond to the general character of a given type description. The similarities between sediments in a particular group do not necessarily indicate a stratigraphic relationship, although this may be true in some cases. Sediment types A, B, and the type C sediments containing shell are considered Holocene; the remaining types are probably of pre-Holocene age.

Table 2. Primary shelf sediment classes.

Type	Lithology	Description
A	Quartz sand	Typically very pale brown (10 yr 7/3)[1], fine to coarse grain size; 1 to 5 percent shell (predominantly *Spisula*), well to poorly sorted; silty in places but predominantly clean.
B	Silty sand and gravel	Typically variable grayish-brown color; shells comprise 1 to 10 percent; generally very poorly sorted, silty, and occurs in thin layers in most places; frequently consists of reworked substrate.
C	Silt and silty clay	Typically gray (5 yr 6/1) but occasionally brownish gray; mostly barren but contains shells in places; washed residues may contain sand, mica, and pieces of vegetation.
D	Clean to silty sand	Typically grayish brown (10 yr 6/1 to 10 yr 7/2); ocassionally yellowish or reddish-yellow very fine to fine sand; generally well sorted; micaceous locally.
E	Sand and gravel	Typically very light gray (5 yr 7/1) but often grayish to reddish brown; very poorly sorted sand, predominantly quartz; granules and pebbles consist mostly of quartz and rock fragments.
F	Quartz sand	Typically very light gray (5 yr 7/1) but often grayish to reddish brown; very similar to type E but with little or no gravel; poorly sorted, quartz predominant mineral.

II. POTENTIAL BORROW AREAS

1. Sand Requirements and Beach Characteristics.

Studies by Krumbein and James (1974), James (1975), and Hobson (1977) have shown that the suitability of sand for beach nourishment is largely dependent on grain size and sorting. Sampling of beach and shoreface sands, native to the Cape May coast,by the U.S. Army Engineer District, Philadelphia (1979) indicates that fill sand should be in the fine to medium range or coarser (0.125 to 0.5 millimeter, 3 to 1 phi) for Cape May city, and at least medium to very coarse sand (0.25 to 2.0 millimeters, 2 to -1 phi) for the shore in Lower Township to the west (Wentworth Scale in Table 1). Identification and selection of the borrow areas described below are based on these criteria.

2. Borrow Areas.

The locations of 16 potential borrow areas where sand judged suitable for beach restoration and nourishment may be recovered are identified by letters in Figure 4. Table 3 provides a summary of the pertinent data for the deposits. The first part of the table contains information for the shoal deposits of Holocene marine sand. Volume calculations have been made for the Holocene marine sand deposits where seismic reflection and topographic control are sufficient for a reasonably reliable estimate. The second part of Table 3 contains data on sites identified by core number where the specified core recovered potentially usable sand, but from deposits which were not associated with any discernible

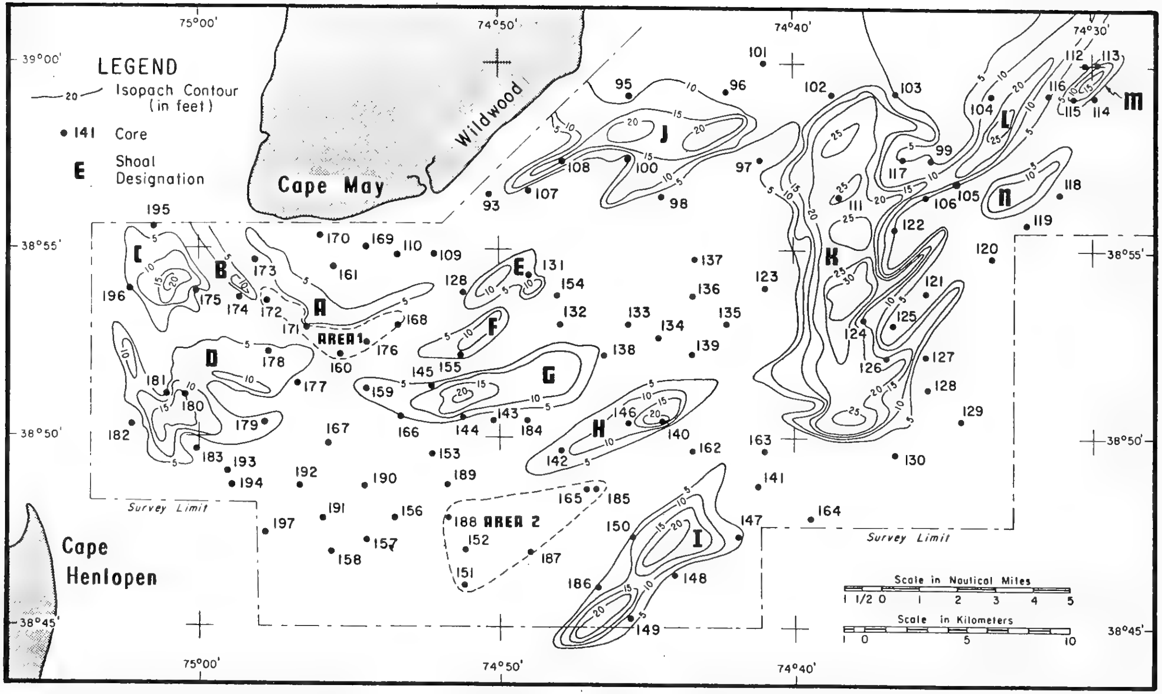

Figure 4. Isopach (thickness) map of the major shoals containing Holocene-age marine sand suitable for beach nourishment. Shoals A to N and areas 1 and 2 are discussed in the text.

Table 3. Summary of potential borrow areas.

[1]Unknown.

topographic or seismic reflection features. For this reason core data could not be projected beyond the immediate area of the core site and no area or volume calculations could be made. Several of these sites contain Holocene marine sand (type A) which does not seem to be associated with a prominent shoal. The remaining sites contain type E of F material which is thought to be pre-Holocene fluvial sediment. All of the pre-Holocene deposits are beneath some overburden, which mostly consists of suitable type A sand. Thus, the combined thickness of both units is considered usable. Many of the cores bottomed in usable material and their thickness are shown as greater than the specified amount of core recovery.

Eleven cores containing usable type E and F material are grouped into areas designated as areas 1 and 2 in Figure 4. It is possible that continuity of these deposits exists throughout the area. If this is true, a potentially usable volume of more than 14.5 million cubic meters of material could be recovered from area 1 and 20.6 million cubic meters from area 2. However, if these are fluvial deposits it seems unlikely that deposition was continuous over such a large area. Additional detailed coring in areas 1 and 2 is necessary to properly define the deposit before these areas can be considered high potential sites for sandfill.

Of the 16 separate borrow areas identified in Figure 4, shoals A,B,C,E,F, J and area 1 should definitely be considered as sources of fill for any projects along the Cape May coast. They are within about 9 kilometers of the coast, all have water depths less than about 12.8 meters (42 feet), and their combined sand resources are estimated to be more than 216 million cubic meters, more than enough to meet projected fill requirements for beach nourishment projects. Brief descriptions of these sites are given below.

a. Borrow Area A and Area 1. Area A (Fig. 4) is an elongate and arcuate shoal (named Prissy Wicks shoal on NOS chart 1219) that semiparallels the coast at the end of Cape May. Area 1 is a rather flat extension of the south flank of the shoal and is composed of fluvial sands that probably underlie the entire Prissy Wicks shoal complex. The seismic data in area A and the seismic and core data in area 1 show that sand about 1.5 meters thick is present; the combined estimated sand resources are more than 28.3 million cubic meters.

b. Borrow Area B. Area B consists of a narrow fingerlike shoal (named North Shoal on NOS chart 1219) adjacent to areas A and 1. Core 174 off the southern flank shows that the shoal is composed of medium to coarse sand underlain at the base by fine-grained sediment.

c. Borrow Area C. Area C is a concentric shoal (Fig. 4) immediately west of area B and about 5.4 kilometers from the western side of Cape May peninsula. The area comprises Round and Middle Shoals (on NOS chart 1219), and the seismic data and core 175 show that it contains up to 6.1 meters of a poorly sorted mixture of fine to very coarse pebbly sand.

d. Borrow Areas E and F. These areas are two closely spaced shoals within 7.2 kilometers of Cape May Inlet; they probably offer the highest potential as sources of nourishment sand. The CERC data show that medium to coarse sand is present to about 3-meter (10 feet) depths and the combined estimated sand volumes are more than 21.3 million cubic meters.

As a result of CERC recommendations, the U.S. Army Engineer District, Philadelphia, conducted additional detailed surveys of area E to evaluate it as a primary source for fill as part of their beach erosion control and storm protection study for Cape May and Lower Township (U.S. Army Engineer District, Philadelphia, 1979). In September 1978, 27 vibratory cores and 47 kilometers of fathometer profiles were collected in a fairly dense matrix with a core spacing of about 305 meters. Analyses of the cores confirmed that clean, medium-grained sands with a median diameter of 0.4 millimeter (1.27 phi) are present to depths of about 3.7 meters (12 feet). The penetration records from the cores also showed that the sands at the base of the shoal are very dense which suggests that marine Holocene type A sediments in the shoal are underlain by fluvial pre-Holocene silty sands.

e. Borrow Area J. Area J is a fingerlike shoal detached from the lower shoreface off Two Mile Beach to the east of Cape May Inlet. Core 108 and the accompanying seismic data show that suitable sand to a thickness of at least 6.1 meters is present and the estimated volume is about 145 million cubic meters, which makes area J the second largest (the largest is Five Fathom Bank in area K, with 472 million cubic meters) potential borrow area in the study area. Although the area offers much promise as a fill source, it is a minimum of 5.4 kilometers from the Cape May beaches and may be better suited to possible future projects along the Wildwood shore.

III. SUMMARY

A geologic study using seismic reflection profiles and sedimentary cores (a maximum of 3.7 meters long) was made of the Inner Continental Shelf region off Cape May, New Jersey, to locate and delineate sand and gravel suitable for beach restoration and maintenance.

Results of the study show that 18 sites identified on isopach maps contain an estimated 1,086 million cubic meters of sand. All but two sites constitute linear and arcuate shoals that are Holocene features composed of clean, marine quartz sand. The shoals are about 6.1 meters thick and appear to rest on a pre-Holocene fluvial surface composed of dense silty sand and gravel.

Six shoals (A,B,C,E,F, and J) and area 1 (Fig. 4) are closest to Cape May beaches and contain about 216 million cubic meters of sand, making them the best sites for future consideration.

APPENDIX A

CORE SEDIMENT DESCRIPTIONS

This appendix contains core sediment descriptions, based on both megascopic and microscopic examination, from sampling locations shown in Figure 2. Sediment color is based on dry samples.

Sediment names are based on the following Wentworth classifications (see Table 1):

Sediment	Size (mm)	Phi
Gravel	>2	<-1
Very coarse sand	1.0 to 2.0	0 to -1
Coarse sand	0.5 to 1.0	1 to 0-
Medium sand	0.25 to 0.5	2 to 1-
Fine sand	0.125 to 0.25	3 to 2-
Very fine sand	0.0625 to 0.125	4 to 3-
Silt and mud	<0.0625	>4
Sorting terms		
Very well sorted		0.35
Well sorted		0.50
Moderately well sorted		0.80
Moderately sorted		1.40
Poorly sorted		2.00
Very poorly sorted		2.60
Extremely poorly sorted

APPENDIX B

GRANULOMETRIC DATA AND CUMULATIVE CURVE PLOTS

This appendix contains the results of CERC's Rapid Sediment Analyzer (RSA) size analyses of 258 sediment samples from 104 cores (Table B-1) in the study area (see Fig. 2). Analyses are based on sand-size fractions only.

The samples are identified by core number and sample interval below the top of the core. Specific locations of the samples from each core are given in Appendix A.

Experience has shown that grain-size values from RSA analyses are consistent and slightly coarser than results of dry sieve analyses of identical samples. To relate these RSA data to other sieve data, empirical relations for converting RSA means and standard deviation to sieve analyses equivalents have been determined. The relationships, developed from RSA and sieve analyses at a 0.25-phi interval, are:

$$\text{mean: } \bar{X}_{\phi \text{sieve}} = 1.0735\ \bar{X}_{\phi \text{RSA}} + 0.1876$$

RSA standard deviation values may be converted to sieve sorting equivalents by the formula:

$$\text{standard deviation: } \sigma_{\phi} \text{ sieve} = 1.4535\ \sigma_{\phi} \text{ RSA} - 0.146$$

Table B-1. Results of RSA size analyses of 258 sediment samples.

Meisburger, Edward P.
Sand resources on the Inner Continental Shelf of the Cape May Region, New Jersey / by Edward P. Meisburger and S. Jeffress Williams. -- Fort Belvoir, Va. : U.S. Coastal Engineering Research Center ; Springfield, Va. : available from National Technical Information Service, 1980.
[40] p. ill : 27 cm. -- (Miscellaneous report -- U.S. Coastal Engineering Research Center ; no. 80-4)
Includes bibliographical references.
About 1,235 square kilometers of the Inner Continental Shelf adjacent to Cape May peninsula was investigated by a seismic reflection and coring survey to assess potential sand and gravel resources for use as fill in beach nourishment and restoration projects.
1. Cape May, New Jersey. 2. Geomorphology. 3. Sand resources. 4. Sand sources. 5. Sediments. 6. Seismic reflection. I. Title. II. Williams, S. Jeffress. III. Series: U.S. Coastal Engineering Research Center. Miscellaneous report no. 80-4.
TC203 .U581mr no. 80-4 627

Meisburger, Edward P.
Sand resources on the Inner Continental Shelf of the Cape May Region, New Jersey / by Edward P. Meisburger and S. Jeffress Williams. -- Fort Belvoir, Va. : U.S. Coastal Engineering Research Center ; Springfield, Va. : available from National Technical Information Service, 1980.
[40] p. ill : 27 cm. -- (Miscellaneous report -- U.S. Coastal Engineering Research Center ; no. 80-4)
Includes bibliographical references
